# FILE: DnB.pl                                                    7-10-2020
#
# SERVICES: D&B Model Railroad Control Program
#
# DESCRIPTION:
#   This program is used to automate operations on the D&B HO scale model
#   railroad. This Raspberry Pi based program and associated electronics
#   replaces the Parallax Basic Stamp based control system. Refer to the
#   program help and the following for documentation related to this new
#   control system.
#
#   Notebook: D&B Model Railroad Raspberry Pi Control
#   Webpage: http://www.buczynski.com/DnB_rr/DnB_Rpi_Overview.html
#
#   For information on the Basic Stamp version, refer to the following.
#
#   Notebook: D&B Basic Stamp
#   Webpage: http://www.buczynski.com/DnB_rr/DnB_Overview.shtml
#
#   This program is written for perl on Raspberry Pi 3.
#
# PERL VERSION: 5.24.1

93  # ========================================================================
94  # DnB Program Start/Stop
95  #
96  # DnB.pl is a perl program that runs under Raspbian operating system; a Debian
97  # based Linux specifically developed for the Raspberry Pi. To prevent possible
98  # corruption of the SD card software, the OS should be properly shutdown prior
99  # to removing power from the Raspberry Pi. Further, the software is designed to
100 # start and run "headless"; that it, without interaction with the Linux CLI for
101 # normal operations. The following describes these processes.
102 #
103 # Startup:
104 #
105 # The /etc/rc.local file is used to automatically launch DnB.pl once Linux has
106 # completed boot. (Attempts to use systemd for startup were unsuccessful, the
107 # program was always killed.) Configure rc.local using the CLI as follows.
108 #
109 #    1. sudo nano /etc/rc.local
110 #    2. Add the following to the file just before the exit 0 line. Change the
111 #       path to the DnB.pl file if stored in a different place.
112 #
113 #       /home/pi/perl/DnB.pl -q
114 #
115 #    3. Use ^O and ^X editor commands to save and exit.
116 #
117 # Note: /home/pi/perl/DnB.pl > /home/pi/perl/DnB.log 2>&1 could be used to
118 #       send DnB.pl console output to a log file. The log file could then be
119 #       monitored using 'tail -f DnB.log' in a command window. Currently,
120 #       there is no code to check/prune the size of this log file.
```

```
#
# During startup, if the shutdown button is held down, the DnB.pl program will
# acknowledge the button hold and exit startup. The RPi will then be usable
# for normal Raspbian CLI/GUI interaction using monitor, mouse, and keyboard.
# Use the CLI/GUI from this point to shutdown Raspbian.
#
# Shutdown:
#
# A momentary contact button is connected across GPIO21 and ground. GPIO21 is
# configured as an input with pullup enabled. This circuit is monitored by
# DnB.pl. Detection of a button press initiates a 10 second delay during which
# five tones will be sounded. At the end of the delay, the Raspbian OS will be
# shutdown using 'sudo shutdown -h now'. Once the Raspberry Pi green activity
# LED is no longer flashing, it is safe to power off the layout electronics.
#
# During the delay period, shutdown can be aborted by another press of the
# shutdown button.

# ============================================================================
# RPi Sound Player
#
# All sound wave files are output, using the $SoundPlayer variable definition,
# by the PlaySound subroutine located in DnB_Yard. The PCM playback volume is
# set to default -1800 (max = 400, min = -10000) during startup. This value
# can be changed using the -v command line option.

# ============================================================================
# Turnout Related Data
#
# The ServoBoardAddress hash holds the I2C address of the servo driver boards.
# It is used to populate the 'Addr' entries in the %TurnoutData hash.

my %ServoBoardAddress = ('1' => 0x41, '2' => 0x42);

# The TurnoutData hash stores the information used to position the turnouts on
# the layout. The storage structure is known as a 'hash-of-hashes'. This type
# of data structure simplifys access by the code. Only a pointer to the hash
# is needed when communicating the dataset to code blocks.
#
#  %TurnoutData (
#     Turnout1 => {                                    Value
#        Pid => <pid of forked MoveTurnout process>     0
#        Addr => <driver_board_I2C_address>,            -
#        Port => <driver_board_servo_port>,             -
#        Pos => <last_servo_pwm_position>,             600
#        Rate => <servo_move_rate_pwm_per_sec>,        450
#        Open => <turnout_open_pwm_value>,             350
#        Middle => <turnout_middle_pwm_value>,         600
#        Close => <turnout_close_pwm_value>,           850
#        MinPos => <minimum_servo_pwm_position>,       300
#        MaxPos => <maximum_servo_pwm_position>,       900
#        Id => <Identification string>                  -
#     },
#     Turnout2 => {
#        ...
#     }
#  );
#
# The following initializes the hash with default data. Default data is used
# to write the initial TurnoutDataFile contents. Thereafter, these values are
```

```
# overwritten during program startup by TurnoutDataFile file load. This allows
# the user to change the operating values for Rate, Open, Close, and Min/Max
# for layout needs. Note, the name keys are case sensitive. A 'Rate' value of
# 450 moves the turnout servo from Open (350) to Close (850) in 1.1 seconds.
#
# Once the servo mechanical adjustments and operational servo positions are
# determined using the TurnoutDataFile file, those values should be entered
# into the %TurnoutData hash below. This ensures that if the TurnoutDataFile
# file is regenerated using the -f option, the operational position values
# will be preserved.
#
# Important: The ~100 hz PCA9685 refresh rate calculation in I2C_InitServoDriver
#            results in MinPos:300 and MaxPos:900 for the SG90 servo. When
#            adjusting turnout point positions, do not exceed these limits.
#            The values shown above will result in full servo motion and
#            rotational rate.

327
328 # Since MoveTurnout is a slow process, each turnout position change is forked
329 # to prevent blocking the main program. A simple fork does not support passing
330 # of child data back to the parent. Since the final turnout position is needed
331 # from the child, a 'piped fork' is used. At fork activation, the child process
332 # pipes STDOUT and STDERR are mapped to the TurnoutData hash, 'Pos' and 'Pid'
333 # respectively, for the turnout being moved.
334 #
335 # Following fork activation, the child process pid is stored in the TurnoutData
336 # hash for the turnout. The turnout move is 'inprogress' until this pid value is
337 # again zero. The child process prints the final turnout position to STDOUT and
338 # zero to STDERR. These values are written directly to the %TurnoutData hash due
339 # to the pipe configurations set at activation.

```
#    Off          Unoccupied block not being approached
#   Green         Approaching unoccupied block
#    Red          Approaching occupied block
#   Yellow        Approaching unoccupied block; subsequent block occupied

# - Signal Control -
#
# The GpioData hash holds the Raspberry Pi GPIO pin data that is used to access
# the driver hardware controlling the layout signals and power polarity relays.
# The pins are manipulated by RPi::WiringPi to communicate with the 74HC595 shift
# register which in turn drives the signal LEDs. The power polarity relays are
# driven directly by the GPIO pins. The Init_SignalDriver code creates the
# necessary pin objects and stores the object pointer in this hash.

# GPIO set to hardware PWM mode.

my %GpioData = (

# RPi::Pin needs numeric value inputs. Defenitions are as follows.
#    'Mode': 0=Input, 1=Output, 2=PWM_OUT, 3=GPIO_CLOCK

# The SignalData hash stores information about the signals. Each entry uses a
# consecutive pair of bits in the shift register; bits 0 and 1 for signal 1,
# bits 2 and 3 for signal 2, etc. A bicolor LED is wired across the bit pair
# and illuminates red for one voltage polarity (e.g. bit 0 high, bit 1 low) and
# green for the opposite polarity (bit 0 low, bit 1 high). If both bits are the
# same state, high or low, the LED is off. This provides the needed signal
# states; off, red, and green. The specific state for each signal is determined
# by the code using the block detector inputs.

# The color yellow is achieved by rapidly switching a signal between red
# and green. The human eye perceives this action as the color yellow. The
# SignalChildProcess performs this by using two internal shift register
# buffers. Yellow signals are red in one and green in the other. The buffers
# are alternately sent to the shift register.

# The bits associated with SignalData 13 and 14 are used for the grade crossing
# signals. See the 'Grade Crossing Data' section below for information as to
```

```
# how these bits are utilized.

# The algorithm used for setting a signal's color is based upon the track plan
# and signalling rules. Each track block, when occupied by a train, results in
# a set of signal indications as described in the %SignalColor hash. The color
# values are derrived by assuming a single occupied track block.

#                                  Signal
# ActiveBlock   S01  S02  S03  S04  S05  S06  S07  S08  S09  S10  S11  S12
# -----------   ---  ---  ---  ---  ---  ---  ---  ---  ---  ---  ---  ---
#    B01        GRN  YEL
#    B02        GRN  YEL
#    B03        RED  RED  GRN  YEL  GRN  YEL
#    B04        YEL  GRN  RED  RED            GRN  YEL
#    B05        YEL  GRN            RED  RED  GRN  YEL
#    B06                  YEL  GRN  YEL  GRN  RED  RED  GRN  YEL  GRN  YEL
#    B07                                     YEL  GRN  RED  RED
#    B08                                     YEL  GRN            RED  RED
#    B09                                                YEL  GRN  YEL  GRN
#    B10                                                YEL  GRN  YEL  GRN

# When multiple track blocks are occupied, color priority is applied since a
# signal might have more than one color indication. For example, if only B03
# is occupied, the color for S03 is green. If both B03 and B04 are occupied,
# S03 could be either green or red. The correct color to display is red. When
# a signal would display more than one color, the following color priority is
# used: Red = highest, Yellow = medium, Green = lowest.

# To accomplish this prioritization, the block sensor inputs are processed three
# times, 1st for green indications, 2nd for yellow indications, and lastly for
# red indications. In this way, red overwrites green or yellow, and yellow
# overwrites green.

# Primary key maps to the %SensorBit hash. The secondary key maps to the
# %SignalData hash.

# - Semaphore Signal -
#
# The SemaphoreData hash holds information related to the Semaphore signal. This
# signal is modeled as the old style moveable flag board semaphore. The lamp in
# this signal is a low voltage incandescent bulb. The lamp is driven by a bit of
# the associated signal bit pair defined in the SignalData hash. The SignalData
# primary key (signal number) is the primary key used in the SemaphoreData hash.

my %SemaphoreData = (
    '08' => {'Servo' => '30', 'InMotion' => 0, 'Lamp' => 'Off'});

# The SemaphoreData hash identifies the TurnoutData servo used with the signal.
# The 'Open' (green), 'Middle' (yellow) and 'Closed' (red) positions of the flag
# board can be adjusted like the turnouts by modifying the TurnoutDataFile file.

# The SemaphoreData hash is also used to persist control data. Due to signal flag
# board motion, multiple calls to the SetSemaphoreSignal code will occur before a
# previously requested color position is completed.

# When setting signal colors, the main code checks the SemaphoreData hash for the
# signal being processed. If present, the SetSemaphoreSignal routine us used for
# setting its color. See the description of this code for further information.

# ============================================================================
# Grade Crossing Data
#
# There are two grade crossings on the DnB model railroad, each with flashing
# signals and one with crossing gates. Across-the-track infrared sensors are
# used to detect train presence. These sensors are mapped to bit positions in
# the %SensorBit hash. At program startup, a dedicated child process is started
# for each grade crossing. The child process is used to handle the signal lamp
# flashing. Gate positioning, and logic to send the 'start' and 'stop' commands
# to the signal child process, is handled by the ProcessGradeCrossing code.

my %GradeCrossingData = (
    '01' => {'Pid' => 0,                  # Pid of child process.
             'AprEast' => '10',           # %SensorBit east approach sensor bit.
             'Road' => '11',              # %SensorBit road sensor bit.
             'AprWest' => '12',           # %SensorBit west approach sensor bit.
             'Signal' => '13',            # %SignalData lamp bits.
             'Gate' => '',                # %TurnoutData gate servo(s).
             'State' => 'idle',           # Current grade crossing state.
             'AprTimer' => 0,             # Approach activity timer.
             'RoadTimer' => 0,            # Road activity timer.

             'SigRun' => 'off',           # Signal lamps active.
             'GateDelay' => 0,            # Not used, no gates for this signal.
             'GateServo' => 0,            # Not used, no gates for this signal.
             'SoundApr' => '4,GPIOB4',    # Approach sound GPIO control bit.
             'SoundRoad' => '4,GPIOB5'    # Road sound GPIO control bit.
            },
    '02' => {'Pid' => 0,                  # Pid of child process.
             'AprEast' => '13',           # %SensorBit east approach sensor bit.
             'Road' => '14',              # %SensorBit road sensor bit.
```

```
            'AprWest' => '15',          # %SensorBit west approach sensor bit.
            'Signal' => '14',           # %SignalData lamp bits.
            'Gate' => '31,32',          # %TurnoutData gate servo(s).
            'State' => 'idle',          # Current grade crossing state.
            'AprTimer' => 0,            # Approach activity timer.
            'RoadTimer' => 0,           # Road activity timer.
            'DepTimer' => 0,            # Departure activity timer.
            'SigRun' => 'off',          # Signal lamps active.
            'GateDelay' => 0,           # Working delay for 'gateLower' state.
            'GateServo' => 0,           # Working servo for 'gateRaise' state.
            'SoundApr' => '4,GPIOB6',   # Approach sound GPIO control bit.
            'SoundRoad' => '4,GPIOB7'   # Road sound GPIO control bit.
           });

# The Signal number maps to the SignalData hash. The grade crossing signals are
# wired to red only Leds, one to each bit of the signal position. When the signal
# is set to 'Red', one lamp will illuminate. When set to 'Grn', the other signal
# Led illuminates. When set to 'Off' both Leds are off. This methodology saves
# 74HC595 shift register bits and facilitates the use of common signal color code.

# The grade crossing with gates maps to the %TurnoutData hash for controlling the
# associated servos. A lowered gate is set by using the 'Close' parameter value
# in the %TurnoutData hash. A raised gate uses the 'Open' parameter value. Adjust
# these values as needed to achieve the desired motion, rate, and end positions.

# Both signals have an associated sound module which produces grade crossing bell
# sound effects. The sound effects are switched on/off by output GPIO bits on a
# sensor board as identified by the 'Sound' parameter in the GradeCrossingData
# hash identifies. The first GPIO activates the 'bell only' sound and the second
# GPIO activates the 'bell + train noise' sound.
#
# Note that the second sound is not used due to sound1/sound2 switching issues
# related to these old sound modules.

# ============================================================================
# Sensor Related Data
#
# The SensorChip hash holds the I2C addresses of the I/O PI Plus boards. The
# mapped address is applied to the sensors referenced in the %SensorBit hash
# below. Each I/O Pi Plus board has twp MCP23017 chips. Each chip has two con-
# figurable 8 bit ports. The sensor initialization code establishes an object
# reference for each chip and stores it in this hash for later use to read
# sensor input. Hash entries DirA (direction PortA), DirB (direction PortB),
# PolA (bit polarity PortA), PolB (bit polarity PortB), PupA (pullup enable
# PortA), and PupB (pullup enable PortB) are used only for chip initialization.
# See MCP23017 data sheet for details.

# The hidden holdover tracks employ sensors which are used to indicate train
# position in the B01 and B02 blocks. These sensors are located close to the
# exit end of these blocks. The sensors drive yellow and red panel LEDs. As
# a train approaches the S2 and S3 sensors, first the yellow and then the red
# LED will begin to flash. In this way, the engineer can stop the train prior
# to activating the S2/S3 sensor; which causes the holdover turnouts to be
# set for holdover departure. The %PositionLed hash holds the LED information
# that is used by the PositionChildProcess code. The primary index of this
# hash maps to the primary index in the %SensorBit hash.

# ============================================================================
# Track Plan: Reverse Loop and Hold-over Tracks

# The trackage involved with this section is hidden and used for train trip
# hold-over and return. Two sidings are available each with a train presence
# block detector (Bx), track power polarity reverse relay (Px), and optical
# sensors (Sx) to detect train movement. Three turnouts (Tx) are used to move
# trains in and out of this section.

#           ----------------- B1/P1 -----------------
#          /                                        \
#         /  ---------------- B2/P2 ----------------  \
#     r1 /  / r2                                  r3 \  \ r4
#        | |                                         | |
#        \ | S2                                      | / S3
#         \|                                         |/
#       T2 \                                        / T3
#           -------------------    ------------------
#                              \  /
#                           T1 |/
#                              | S1
#                              |
#                             B3
#                              |
#                              ~

# Reverse loop operation requires that for an inbound or outbound operation,
# with respect to a siding, the rail polarity must match mainline rail polarity.
# This rail polarity match is required only while power drawing portions of a
# train are in transit across the siding rail gaps.

# In operation, a train on the mainline approaches the reverse loop. It is
# detected by sensor S1. If block detector B1 is inactive, T1, T2, and P1 are
# set to direct the train to siding B1. If block detector B1 is active, T1, T3,
# and P2 are set to direct the train to siding B2. If B2 is also active, the
# train wreck warning is sounded. Turnouts are used this way to take advantage
# of the 'straight' side of hidden turnouts T2 and T3 to minimize derailments.
# Trains always move clockwise through siding B1 and counter-clockwise through
# siding B2.

# A train leaving B1 or B2 will be detected by S3 or S2 respectively. T1/T3/P1
# or T1/T2/P2 are set to direct the train back onto the mainline.

# For an inbound or outbound operation, it is necessary to disable acting on S1
# active indications following the initial one. For the inbound direction, this
# prevents turnouts from changing as the block detector B1/B2 begins reporting
# the presence of a train. In the outbound direction, it prevents assumption of
# an inbound train and T1 operation.

# Stopping or backing a inbound or outbound train will have no effect on these
# operations unless the outbound sensor S2 or S3 has been reached. If so, the
```

```
# turnouts and block power polarity will be set for an outbound condition and
# incorrectly set for a backup operation. A train should not be backed up once
# it is more than half way into a siding.

# An operational deficiency was noted in this track section. Train movement
# through these turnouts following correction of derailments was troublesome
# due to the automatic turnout positioning. With the RPi design, a four button
# keypad is added to permit route selection. The buttons correspond to the
# routes (r1-r4) leading from the B3 mainline to each end of the B1 and B2
# sidings.

# Following a holdover button press, the three turnouts will be positioned for
# the specified route. A tone will be sounded and an active indicator on the
# keypad will be illuminated. The route will remain active until:
#
#   1. One of the four buttons is pressed.
#   2. No S1, S2, or S3 sensor activity is detected for 30 seconds.

# Track Plan: Midway Sidings

#                                              S5   T5
#          ------------------ B4 ---------------------- B3 -- ~
#         /                                          /
#        /   ---------------- B5 ------------------
#       /   /
#       \  | S6
#        \ |
#         \| T6
#          |
#          B6
#          |
#          ~

# The track involved with this section provides a place for mainline trains to
# pass each other. The associated turnouts simulate proto typical turnouts that
# are "spring loaded" to a specific position. When entering, the train is always
# directed to a specific track. When exiting, the turnout points are positioned
# to permit train passage. Once the last car of the train passes through the
# turnout, its points are set back to the "normal" position.

# Normal position routes a train approching T5 from B3 to siding B5. A train
# approaching T6 from B6 is routed to siding B4. A train leaving B4 or B5 will
# be detected by sensors S5 or S6 respectively. The points of T5 or T6 will be
# set to direct the train back onto the mainline. A retriggerable timeout is
# used to debounce the S5 and S6 sensor inputs. Three seconds after the last car
# transits the sensor, the turnout is repositioned to "normal".

# Track Plan: Yard Approach Wye

#            -------- B10 -------
#           /                    \
#          /--------- B9 ---------\
#         |                        |

#          \                      /
#           \         P3         /
#            \                  /
#         S8  \                /  S9
#              \-----   ------/
#                T7  \ /
```

```
781 #                    |
782 #                   B6
783 #                    |  S7
784 #                    ~
785
786 # The track involved with this section provides a "wye" turnout; the legs of
787 # which are approach tracks leading to opposite ends of the yard. This forms a
788 # reverse loop that includes B7 through B10 and all of the yard tracks. The
789 # blocks are individual only for the purpose of signaling. Tracks leading to
790 # and including the yard tracks from T7 are wired to polarity control relay P3.
791
792 # Turnout T7 is only partially controlled. The last set route will be used for
793 # trains in B6 approaching T7 unless manually changed by the train engineer. The
794 # T7 turnout points will be set automatically for B7 or B8 trains approaching T7
795 # when detected by S8 or S9. The power polarity relay P3 will be set based on the
796 # position of T7 to yard track power polarity matches B6 track power.
797
798 # In all cases, it is not necessary to "ignore" sensor inputs in either direction
799 # of travel. Detections by S8 or S9 following S7 will not change T7 or P3 from
800 # their current states. The same is true for S7 detections following S8 or S9.
801
802 # The TrackData hash, primary key sensor number, stores information that is used
803 # to set turnouts and track power polarity based on train movement that activates
804 # sensor (Sx) and block (Bx) input.

889
890  # The T5 and T6 toggle buttons provide for manually toggling the position of
891  # the respective turnout. This functionality is used for special train operations
892  # involving this section of track. Button input is ignored if the respective
893  # turnout is performing an inprogress timing operation. After manually toggling
894  # T5 or T6 to the "non-normal" position, these turnouts will automatically reset
895  # to their normal position once the train completes its transit of the turnout.
896
897  # Turnouts T5 or T6 can be "locked" into the non-normal position by pressing the
898  # appropriate turnout toggle button a second time within .5 second of the first
899  # depression. The turnout will remain in the non-normal position until manually
900  # set to the normal position using the respective toggle button.
```

```
#
# Both T5 and T6 cannot be locked at the same time; a derailment would occur.
# Locking either T5 or T6 permits a train to be stopped on one of the sidings
# for an extended period of time and not interfere with mainline traffic
# movements using the other track. To unlock a turnout, double press the turnout
# toggle button.

# Buttons are provided for manually toggling the position of turnout T7. This
# functionality is used for selecting the desired approach track to the yard.
# Button input is ignored if the Wye retriggerable timeout counter is non-zero
# indicating that a train is transitting the turnout. Manual change will be
# ignored until one second after the last active detection by S7, S8, or S9.

# ============================================================================
# Yard Route Data
#
# The YardRouteData hash holds information used to set the turnouts (Tx) of the
# yard and approach tracks. The following diagrams illustrates the track and
# turnouts involved.
#                             ~
#                             | T7
#                             |\
#    ------------------------- -------------------------------------
#   /                                                               \

#          \-\---------\T13----------- 4 ------T14/---------/ /
#             \                                             /
#              \---------------------- 3 ----\-------------/ T27
#                                        T26 \            /
#                                             \--- 16 ---/
#
# Yard and approach tracks are assigned a number; 1 through 16. The track
# number corresponds to the numbered keypad buttons. A route is specified
# by keying in two track numbers. The first number entered is the "from"
# track. It is the track currently occupied by the train. The second number
# entered is the "to" track. It is the desired destination track for the
# train. Once both numbers are input, the turnouts for the specified route
# will be set appropriately. Key combinations that do not correspond to a
# valid route will be ignored and an error tone will sound.
#
# Note: The keypad returns 0-F and these numbers are also used in the
# %YardRouteData index keys. These hexadecimal numbers correspond to tracks
# 1-16.
#
# Keying in the same number for the "from" and "to" tracks will set the
# turnouts to route just the specified track. This is useful for the
# following operations.
#
# Track 3-5: Will set all turnouts on these tracks to their normal
#            (straight) position.
```

```
# Track 16:  Will open the four turnouts T12 through T15 for a "run
#            around" operation. Consecutive track 16 entry will close
#            all four turnouts.
#
# There are some special cases that must be handled. These involve from/to
# tracks that are dependent on direction. Since direction is not known, the
# code initially sets turnouts for a left to right movement relative to the
# above diagram. If the same from/to command is consecutively entered, the
# right to left movement is set.
#
#    Track 3 to 16:
#       Initial     - T26
#       Consecutive - T27
#    Track 5 to 4:
#       Initial     - T12 and T13
#       Consecutive - T15 and T14
#    Track 4 to 5:
#       Initial     - T14 and T15
#       Consecutive - T13 and T12
#
# Only the turnouts for the selected route will be affected, all other
# turnouts retain their current position. Turnout positions are stored as
# they are set during operations. This information is referenced during
# subsequent operations to skip the setting of turnouts already in the
# proper position.
#
# To facilitate keypad entry, an indicator is positioned on the keypad.
# This indicator will be illuminate when the first track number is entered.
# It will extinguished when the second track number is entered.
#
# The %YardRouteData primary index is made up of a 'R' and two hexadecimal
# characters. The first character is the "from" track number. The second
# character is the "to" track number. The value for each index is a comma
# separated list of turnout numbers and their required position.

my %YardRouteData = (

             'T14:Close',
    'X14' => 'T11:Open,T10:Open,T12:Close,T13:Close,T16:Close,T17:Close,' .
```

```
            'T15:Close,T14:Close');

# ============================================================================
# Simulation Data
#
# The SimulationData hash holds information that is used to simulate the movement
# of a train over the layout when the -a option is specified on the DnB.pl CLI.
# Each hash entry is a step of that movement and consists of sensor values and a
# time period. This hash is populated and used by code in DnB_Simulate.pm.
#
my %SimulationData = ();

# ============================================================================
# Child Process Priority
#
# A number of the processing functions are performed as child processes to the
# main code. Child process priority (fork os_priority) is used to balance overall
# program flow. For example,
#
#   * SignalChildProcess is timing sensitive due to the toggling of red/green
#     to produce a yellow signal indication.
#   * Turnout open/close operations would cause main code blocking until the
#     stepping of an inprogress operation completes.
#
# Normal linux priority for a program is 0. Priority above normal is set with a
# positive value. Priority below normal is set with a negative value.
#
# Process               Priority
# ------------------    --------
# SignalChildProcess       6
# ButtonChildProcess       4
# KeypadChildProcess       4
# GcChildProcess           2
# MoveTurnout              1
# PositionChildProcess     0
# Main code                0

# ============================================================================

===== Help for $ExecutableName ================================================
This program is used to automate operations on the D&B HO scale model railroad.
This Raspberry Pi based program and associated electronics replaces the Parallax
Basic Stamp based control system. Refer to the following for details.

Notebook: D&B Model Railroad, Raspberry Pi Control
Webpage: http://www.buczynski.com/DnB_rr/DnB_Rpi_Overview.html

For information on the Basic Stamp version, refer to the following.

Notebook: D&B Basic Stamp
Webpage: http://www.buczynski.com/DnB_rr/DnB_Overview.shtml

This program is coded in perl and runs under the Raspbian OS. The RPI::WiringPi
perl module, written by Steve Bertrand, interfaces the various Raspberry Pi
hardware functions, e.g. serial communication and GPIO, with perl.

The shutdown button must be used to properly shutdown the Raspbian OS prior to
removing power from the layout electronics. This is important to prevent possible
corruption of the SD card software. It is safe to power off the electronics once
```

the green activity LED on the end of the lower board, the Raspberry Pi, does not flash for about 5 seconds. The DnB program can be safely terminated using ctrl+c when manually started from the command line.

The DnB.pl program is configured to start automatically as part of Raspbian OS boot. Hold down the shutdown button prior to, and during power-on to cause the DnB program to terminate without OS shutdown.

The Raspberry Pi serial port can be used to communicate messages to a monitor terminal. A USB->COM device such as the Adafruit P954 cable, which also performs level shifting, is used to connect the Pi to an external computer running a terminal emulator program. e.g. PuTTy or terraterm. GPIO pin connections on the Pi end are: 6 (Gnd, blk), 8 (Txd, wht), 10 (Rxd, grn). Set terminal emulator to 115200,8,N,1 for the COM port being used on the USB end.

This control system uses SG90 hobby servos to better model proto-typical turnout movement. Two Adafruit I2C 16-Channel servo boards are used. The individual servo positions are controlled by the pulse width values set in these driver boards by the DnB program. Last position information for each turnout is saved as part of normal shutdown. It is used for servo positioning on the subsequent power up or program restart. The crossing gate and semaphore servos are also controlled through by these driver boards.

The file holding the servo position information, TurnoutDataFile.txt, can be user modified using a text editor. Typically, the 'Open', 'Close', and 'Rate' values are adjusted for the desired turnout operation. The changed values will be used on the subsequent program start. Should the file become hopelessly corrupt, it can be restored to defaults using the -f option. A backup of the existing file will be made.

The trackside signals are controlled using 74HC595 shift registers. Since each signal lamp utilizes a single red/green LED, internally wired back-to-back, two shift register bits are needed for each lamp to obtain the desired four state indications; off, red, green, and yellow. This is similar to the previous Basic Stamp design. The grade crossing signal lamps are also controlled by this shift register.

The block detector, sensor, and keypad inputs are interfaced using I2C 32 Channel Pi expansion boards. These boards use the Microchip MCP23017. The keypads are used for turnout positioning input.

There is copious documentation contained in the program code which explains the design and operation in greater detail. All programs can be viewed in a text editor or the program listing binder.

USAGE:

```
   $ExecutableName [-h] [-q] [-f] [-i] [-d <lvl>] [-c] [-o|-m|-c <num>]
          [-s [r]<range>] [-t [r]<range>] [-b <range>] [-g 1|2] [-k 1|2]
          [-n] [-p] [-r] [-v <num>] [-x] [-y] [-z] [-a]

   -h           Show program help.

   -q           Runs the program in quiet mode. Suppresses all console
                messages. Useful when running the program using autostart.

   -d <lvl>     Run at specified debug level; 0-3. Higher level increases
                message verbosity. Uncomment Forks::Super::DEBUG statement
                in main code to see Forks related debug output. Note that
                level 3 causes output of child process messages. This may
                result in a flood of message output until DnB.pl is ctrl+c
```

```
                terminated and then restarted with a lower debug level.

    -i          Detect and display the I2C addresses; runs i2cdetect in
                the background. Expected active addresses are:

                   Block detectors: 0x20
                   Track sensors:   0x21
                   Yard keypad:     0x22
                   Button input:    0x23
                   Turnouts 1-16:   0x41
                   Turnouts 17-32:  0x42
                   Not Used:        0x70

    -y          Send console output to the serial port device.
                Device: $SerialDev   Baud: $SerialBaud

    -f          Backup existing TurnoutDataFile.txt file, if any, and
                create a new file with default values. The program exits
                once the file is created.

    -x          Disable shutdown button check during power on. Used for
                testing when button hardware is not physically connected.

    -z          Enable toggle of GPIO20_TEST pin. Used to view main loop
                timing on a scope. Each code section toggles the GPIO
                state.
                   A - Top of loop          G - Process Signals
                   B - Read sensors         H - Process Yard Route
                   C - Process holdover     I - Read keypad
                   D - Process midway       J - MidwayTrack
                   E - Process wye          K - WyeTrack
                   F - Grade Crossing (2)   L - Shutdown button

    -o|m|c <num> Set the specified servo to its open, middle, or closed
                position. Used for servo mechanical adjustments. Program
                exits once position is set. <num> = 0 sets all servos to
                the specified position.

    -b <range>  Run sensor bit test. <range> specifies the chip numbers
                to use, 1 thru 4. e.g. 1 (chip 1), 1,2 (chips 1 and 2),
                1:4 (chips 1 thru 4). The associated sensor bits are read
                and displayed. This test runs until terminated by ctrl+c.

    -g 1|2      Run grade crossing test using the specified crossing,
                1, 2, or both (comma separated). The grade crossing lamps
                are flashed and gates raised and lowered. This test runs
                until terminated by ctrl+c.

    -k          Run the keypad test; pressed buttons will be displayed.
                The 1st entry LED will toggle for each 4x4 keypad button
                press. Single/double button presses on the 1x4 keypads
                will also be displayed. This test runs until it is
                terminated by ctrl+c.

    -n          Run sensor tone test; all sensors are included. An ID
                number of tones sound when a sensor becomes active and
                a double tone sounds when the sensor becomes inactive.
                This facilitates sensor operability testing at remote
                layout locations; e.g. by manually blocking an IR light
                path. This test runs until terminated by ctrl+c.
```

```
1261
1262     -p           Run the sound player test. Used to select and audition
1263                  the available sound files. This test runs until it is
1264                  terminated.
1265
1266     -r <range>   Run the power polarity relay test. <range> specifies the
1267                  relay to test; 1, 2, or 3. Specify 0 to test all relays.
1268                  The relay is energized for 5 seconds and de-energized for
1269                  5 seconds. Test runs until it is terminated by ctrl+c.
1270
1271     -s <range>   Run signal test. <range> specifies the signal numbers to
1272                  use, 1 thru 12. e.g. 1 (signal 1), 1,5 (signals 1 and 5),
1273                  1:5 (signals 1 thru 5). Preface with 'r' (r1:5) to test
1274                  the specified signals in random instead of sequential
1275                  order. <range> specified as Red, Grn, Yel, or Off will
1276                  set all signals to the specified condition. <range>
1277                  specified as color:nmbr will set the specified signal to
1278                  the specified color. Preface with 'g' to include grade
1279                  crossings 1 and 2. This test runs until terminated by
1280                  ctrl+c.
1281
1282     -t <range>   Run turnout test. <range> specifies the turnout numbers
1283                  to use, 1 thru 29. e.g. 1 (turnout 1), 1,5 (turnouts 1
1284                  and 5), 1:5 (turnouts 1 thru 5). Preface with 'r' (r1:5)
1285                  to test the specified turnouts randomly instead of sequen-
1286                  tial order. Add 'w' (w1:5, wr1:5) to wait for the opera-
1287                  tion to complete before staring another. <range> specified
1288                  Open, Middle, or Close will set all turnoutss to the
1289                  specified position. <range> specified as position:nmbr
1290                  will set the specified turnout to the specified position.
1291                  This test runs until terminated by ctrl+c.
1292
1293     -v <num>     Sets the sound volume to the specified percentage value;
1294                  1-100. Default ${AudioVolume}% is used when not specified.
1295
1296     -a           Simulation mode. This test simulates train movements and
1297                  turnout operations on the layout. The default 'EndToEnd'
1298                  simulation runs until terminated by ctrl+c. Sensorbits,
1299                  yard routes, and turnout positions that are stored in the
1300                  %SimulationData hash are used instead of the actual layout
1301                  input. In this mode, the operational code is exercised
1302                  without actually running a train on the layout. Refer to
1303                  the %SimulationData hash for details. Use debug level 0 to
1304                  display additional simulation data on the console.
